

# Introduction

Phonotactic Language Recognition (PLRE) predicts the language spoken in a sample of speech using a sequence of phonemes, however modelling these sequences have some challenges:

- . Mismatch between the vocabulary of the phoneme recognizers and the languages to recognize.
- . Overlapping of phonemes and n-gram units in different languages.
- . Large sequences and scattering issues due to high order n-grams.

### Contributions

- . We propose the use of transformer encoder architecture and a language classifier on top to perform PLRE.
- . The integration of a **sliding attention window** to handle long input sequences.
- . We compare the use of two phoneme recognizers and two Sub-unit tokenizers to perform PRLE.

## Database

. We used the Kalaka-3 database which contains clean and noisy audio recordings for 6 highly similar languages such as Spanish, Portuguese, Galician, Catalan and others.

# Proposed System

### Transformer-based Encoder

- 1. The speech signals are used as input to a phoneme recognizer, we compare the Brno vs Allosaurus phoneme recognizers.
- 2. We use 3-gram phonetic units with a sub-unit tokenizer, we compare Byte Pair Encoding vs Word Piece .
- 3. The n-gram sequences are the input of the transformer encoder which implements a **sliding window** approach.
